

Dental X-rays, or radiographs, are used to detect abnormalities in the teeth and bones of the face. Xrays are a necessary component of a complete oral exam. Without them, there is no way to detect dental decay or tumors of the bones when they are in their early stages. In both cases, early detection is critical to successful treatment. The dentists at Dental Visions are committed to minimizing the number of X-rays taken on their patients while ensuring that a complete oral exam is performed annually. Contact Dental Visions for more information on dental X-rays.
